Main Takeaway:

An actor critic RL algorithm can be used to train an agent which can define mechanical parameters of a flexible system to maximize performance given a consistent control input.

Extended Abstract:

Legged systems have many advantages when compared to their wheeled counterparts. For example, they can more easily navigate extreme, uneven terrain. However, there are disadvantages as well, including dramatically lower energy efficiency. ~~A potential solution to this problem is the inclusion of non-rigid components within the locomotive system.~~ Research has been conducted that shows using flexible components in operating legged locomotive systems not only increases their efficiency but also their performance [1].

Flexible systems are highly non-linear ~~in nature~~ and are therefore difficult to develop controllers for using traditional methods. Trading flexible links for flexible joints is a mechanical solution which has been studied to solve some of the difficulties ~~found in developing a controller for flexible systems~~ [2]. However, even though these types of systems are easier to model, they do not represent the full capability of truly flexible systems.

Because of the difficulties encountered in modeling flexible systems, control methods have been proposed that use neural networks to represent the non-linear model of the systems and/or implement the control strategy itself. One of these methods is reinforcement learning. Beyond tasking a reinforcement learning algorithm with properly controlling a highly non-linear system, it can also be used to learn mechanical parameters such as the size and flexibility of links. Previous work has shown that such a method ~~used on rigid systems~~ is successful at defining both mechanical parameters and control strategies [3], [4]. In addition to methods which seek to use reinforcement learning to concurrently generate design parameters and control strategies, there are methods which use evolutionary strategies to accomplish the same goal [5].

In this work, rather than training both mechanical design and control strategies, a reinforcement learning algorithm is tasked with ~~training an agent~~ to find only mechanical parameters ~~within~~ a system that has a predetermined control input. The proposed method optimizes the design parameters so that the given control input accomplishes the task.

A mass-spring-damper environment is used to represent a flexible single-legged system, which is tasked with jumping as high as possible given a consistent input defined in [6]. An actor-critic algorithm is utilized to train an agent to modify the spring constant within the environment to maximize jump height. The reward signal used during the training of the neural networks is directly coupled to the height which the single-legged system jumps to.
